Solution gas drive reservoirs Oil reservoirs that do not
initially contain free gas but develop free gas on pressure
depletion are classified as solution gas drives. The solution
gas drive mechanism applies once the pressure falls below
the bubblepoint. Both black- and volatile-oil reservoirs are
amenable to solution gas drive.

The Big Butte Field is a solution gas-drive reservoir that is
under consideration for a waterflood project. The volumetric
calculations of the field indicate that the areal extent of the
field is 1612.6 acres. The field is characterized by the
following properties: Thickness $h = 25$ ft Porosity = 15%
Initial water saturation $S_{wi} = 20\%$

A solution gas drive reservoir is one in which the principal drive mechanism is the expansion of the oil and its originally dissolved gas. The increase in fluid volumes during the process is equivalent to the production (Dake, 1978). This is due to the fact that no extraneous fluids or gas caps are available to replace the gas and oil

Types of Reservoir Drive Mechanisms. The various types of reservoir drives include: Water drive; Solution gas drive; Gas cap drive; Gravity drive; Rock compaction drive; Combination drive; All of these options are possible for any given reservoir, but not all of them are always available to be manipulated. Some reservoirs combine two or more of these drive mechanisms, which is the case in a combination drive.

Solution Gas Drive The reservoir contains oil initially above its bubble point pressure, as the production continues the removal from the reservoir of the produced oil will be compensated by an expansion of the oil left in place. This will lead to a depletion in pressure and eventually it will drop below the bubble point.

The more gas there is in solution, the more compressible the oil. In oil reservoirs with little or no water drive, reservoir energy to drive the oil toward the wellbore can be supplied by expansion of the oil due to gas expanding in solution. This is a solution gas (or dissolved gas or depletion) drive.

Solution gas drive. In a solution (or dissolved) gas drive reservoir, the oil-bearing rock is completely surrounded by impermeable barriers. As the reservoir pressure drops during production, expansion of the oil and its dissolved gas provides most of the reservoir's drive energy. Additional energy is obtained from the expansion of the rock and its associated water.

Gas cap reservoirs produce very little or no water. The recovery of gas cap reservoirs is better than for solution drive reservoirs (20% to 40% OOIP). The recovery efficiency depends on the size of the gas cap, which is a measure of how much latent energy there is available to drive production, and how the reservoir is

External gas drive mechanism has many characteristics, reservoir method accounts for the vertical pressure and saturation gradients, and the secondary gas cap, The thickness of the secondary gas cap varies with pressure in solution-gas drive reservoirs and can be estimated with good accuracy using an idealized saturation gas injection, and oil is displaced by injected gas, This mechanism is referred to as external gas drive mechanism.

Solution gas drive in heavy oil reservoirs (with viscosity in the range of 10 to 1,000 poise and API gravity in the range of eight to 15), which is often referred to as cold production, has a long production history in Canada.

~~Mechanisms of Solution Gas Drive in Heavy Oil Reservoirs ...~~

Production from some of the heavy oil reservoirs in Canada and Venezuela has led to unexpectedly high oil rates and recoveries under solution-gas drive. In an early paper, Smith (1) reported this behaviour in the heavy oil reservoirs of the Lloydminster area, Canada.

(Tarek, 2001) This low recovery suggests that large quantities of oil remain in the reservoir and, therefore, solution gas drive reservoirs are usually considered the best candidates for secondary recovery applicants
